This document contains information, which is proprietary to TEWS TECHNOLOGIES GmbH. Any reproduction without written permission is forbidden.

TEWS TECHNOLOGIES GmbH has made any effort to ensure that this manual is accurate and complete. However TEWS TECHNOLOGIES GmbH reserves the right to change the product described in this document at any time without notice.

TEWS TECHNOLOGIES GmbH is not liable for any damage arising out of the application or use of the device described herein.

Style Conventions

Hexadecimal characters are specified with prefix 0x, i.e. 0x029E (that means hexadecimal value 029E).

For signals on hardware products, an 'Active Low' is represented by the signal name with # following, i.e. IP_RESET#.

Access terms are described as:

W	Write Only
R	Read Only
R/W	Read/Write
R/C	Read/Clear
R/S	Read/Set

1 Product Description

The TCP863 is a standard 3U 32 bit CompactPCI module with four high speed serial data communication channels. It is the successor of the discontinued TCP862, providing similar functionality and full connector and pin-out compatibility.

The TCP863-10 provides front panel I/O via HD68 SCSI-3 type connector and TCP863-20 additionally provides rear I/O via J2.

The serial communication controller is implemented in FPGA logic, along with the bus master capable PCI interface, guaranteeing long term availability and having the option to implement additional functions in the future.

Each channel has receive and transmit FIFOs of 512 long words (32 bit) per channel for high data throughput.

Data transfer on the PCI bus is handled via TCP863 initiated DMA cycles with minimum host/CPU intervention.

Several serial communication protocols are supported by each channel, such as asynchronous, isochronous, synchronous and HDLC mode.

A 14.7456 MHz oscillator provides standard asynchronous baud rates. A 24 MHz and a 10 MHz oscillator are provided for other (synchronous) baud rates.

Each channel provides various interrupt sources, generated on INTA. The interrupt sources can be enabled or disabled individually.

Multiprotocol transceivers are used for the line interface. The physical interface is selectable by software, individually for each channel as EIA-232, EIA-422, EIA 449, EIA-530, EIA-530A, V.35, V.36 or X.21.

The following signals are provided by the TCP863 for each channel at the front panel I/O via an HD68 SCSI-3 type connector and at rear I/O via J2 connector:

Receive Data (RxD +/-), Transmit Data (TxD +/-), Receive Clock (RxC +/-), Transmit Clock (TxC +/-), Ready-To-Send (RTS +/-), Clear-To-Send (CTS +/-), Carrier-Detect (CD +/-) and GND. Additionally serial channel 3 provides Data-Set-Ready (DSR3 +/-) and Data-Terminal-Ready (DTR3 +/-) at the front I/O connector.

A serial EEPROM is used to store detailed board information by software and special configuration parameters.

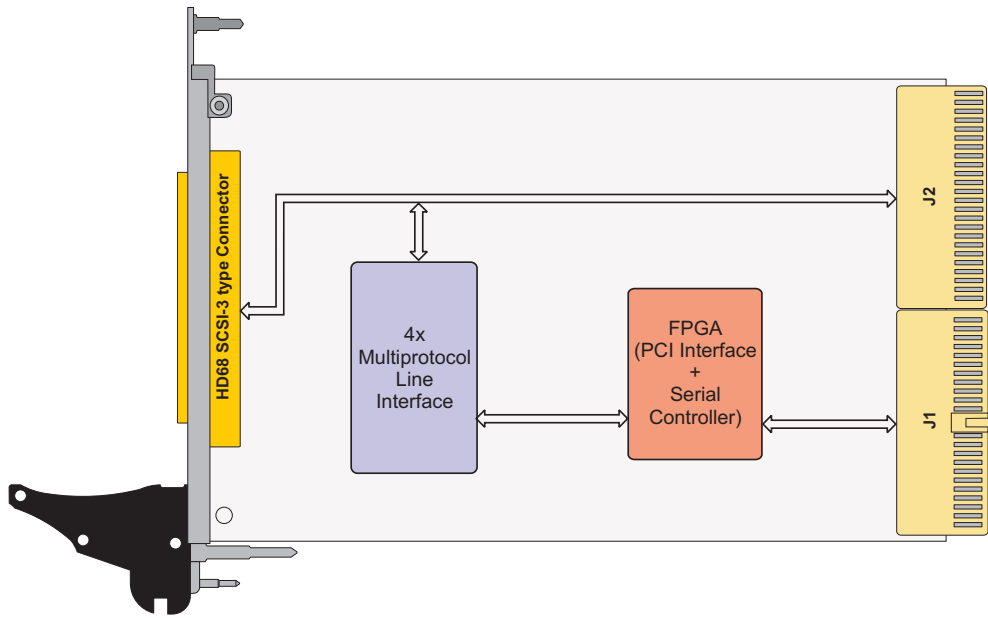

Figure 1-1 : Block Diagram

2 Technical Specification

Logic Interface	CompactPCI 3U 32 bit conforming to PICMG 2.0 R3.0	
Serial Controller with Integrated PCI Interface	XC3S1500-4FG(G)320I Spartan-3 FPGA (Xilinx) with PCI-Core (Xilinx)	
PCI I/O Signaling Voltage Keying	+3.3V and +5.0V	
Serial Interface		
Number of Channels	4	
Physical Interface	LTC1544/LTC1546 (Linear Technology) Multiprotocol chip set, software-selectable, on-chip cable termination	
ESD Protection	4kV	
FIFO	Receive and transmit FIFOs with 512 DWORD per channel (16 KByte in total); additional 16 Byte SCC FIFOs per channel and direction	
Maximum Data Rate	10 Mbit/s (synchronous) 2 Mbit/s (asynchronous) 2 Mbit/s (with clock recovery using DPLL)	
Interrupts	Using PCI INTA for all channels, on board Interrupt Status Register	
I/O Connector	Front panel HD68 SCSI-3 Type Connector (AMP 787082-7 or compatible) TCP863-20: 110 pos. CompactPCI Back I/O Connector	
Physical Data		
Power Requirements	300mA typical (no cable mode) @ +5V DC 900mA typical (V.35 mode) @ +5V DC	
Temperature Range	Operating	-40°C to +85 °C
	Storage	-40°C to +125°C
MTBF	684.000 h MTBF values shown are based on calculation according to MIL-HDBK-217F and MIL-HDBK-217F Notice 2; Environment: G _B 20°C. The MTBF calculation is based on component FIT rates provided by the component suppliers. If FIT rates are not available, MIL-HDBK-217F and MIL-HDBK-217F Notice 2 formulas are used for FIT rate calculation.	
Humidity	5 – 95 % non-condensing	
Weight	131 g	

Figure 2-1 : Technical Specification

3 Functional Description

Data transfers for each direction are handled via PCI DMA transfer. The transfers are controlled via linked lists of descriptors. See the following chapter for a more detailed description of the descriptor and data structures.

The interrupt handling / operation concept is basically the same as on the TCP862, e.g. the Interrupt Queue concept is maintained.

The FIFO structure is slightly different to the TCP862. There is a common interrupt vector FIFO, however, there are dedicated data FIFOs for each channel and direction (not a common central FIFO that is splitted between the channels as on the TCP862).

The register map and register structure in the PCI target space is basically the same as on the TCP862.

The data is not swapped by the DMA Controller, it is always stored in little endian format.

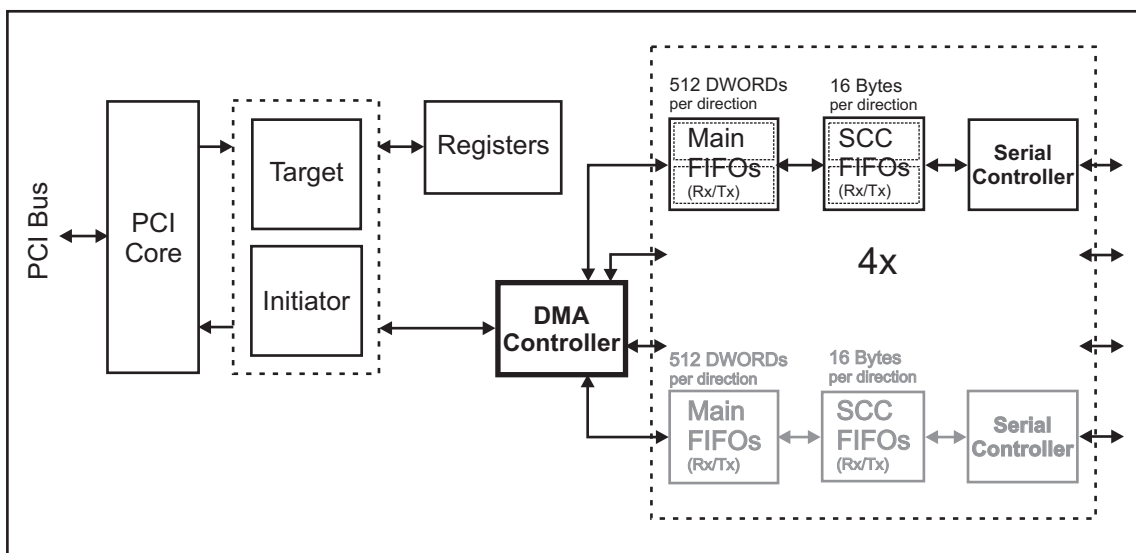

Figure 3-1 : FPGA On-Chip Block Diagram

3.1 DMA Controller

The CPU prepares linked lists for transmit and receive channels in the shared memory. These may be handled by dynamically allocating and linking descriptors and buffers as needed during runtime or by static predefined memory structures e.g. ring-chained-lists (the 'last' descriptor points back to the first descriptor). A mix of predefined descriptor lists but dynamically handled data buffers may also be an appropriate solution. This strategy depends on the specific application. The DMAC provides multiple control mechanisms supporting all of these combinations in an efficient way.

The descriptors and data buffers can be stored in separate memory spaces within the 32-bit address range allowing full scatter/gather methods of assembling and disassembling of packets.

Each descriptor contains a 'next descriptor address' field to implement the linked list. Because the DMA controller cannot distinguish between valid and invalid addresses, a 'Hold' mechanism is needed to prevent the DMA controller from branching to invalid memory locations.

Two alternative control mechanisms are provided to detect and handle descriptor list end (Hold) conditions:

- Hold bit control mode
- Last descriptor address control mode

The Control Mode applies to all DMA channels transmit and receive and is selected via bit 'CMODE' in Global Mode Register GMODE.

An HDLC frame may fit in one buffer connected to one descriptor or it may be split to several buffers each associated with linked descriptors. A 'frame end' indication (FE bit) will be set in each descriptor which points to the last buffer of one HDLC frame.

The 'frame end' indications are stored in the internal FIFOs influencing the FIFO control mechanisms. Therefore 'frame end' indications (FE bit) are also used in non frame oriented protocol modes such as ASYNC mode. They are referred to as 'frame end/block end' indication in the following chapters.

3.1.1 DMAC Transmit Descriptor Lists

Each transmit descriptor consists of 4 consecutive DWORDs located DWORD aligned in the shared memory. The first 3 DWORDs are written by the host and read by the corresponding DMA channel using a burst transaction, when requested to do by the host either via an 'AR' (Action Request) command or a transmit poll command or after branching from previous transmit descriptors. They provide information about the next descriptor in the linked list, the attached transmit data buffer and its size, as well as some control bits.

The fourth DWORD is written by the DMA channel indicating that operation on this descriptor is finished.

The CPU will write the address of the first descriptor of each linked list to a dedicated Base Address Register (BTDAi) during initialization procedure. The corresponding DMA channel starts serving the descriptor at these addresses.

3.1.1.1 Transmit Descriptor

DWORD	31	30	29	28..16	15..0
0	FE	HOLD	HI	NO	0
1	Next Transmit Descriptor Pointer				
2	Transmit Data Pointer				
3	0	C	0		

Figure 3-2 : Transmit Descriptor

FE: Frame End, set by the host

It indicates that the current transmit data section (addressed by Transmit Data Pointer) contains the end of a frame (HDLC) or the end of data block (ASYNC). When transferring the last data from this transmit data section into the internal FIFO the DMAC marks this data with a 'frame end / block end' indication bit.

GMODE.CMOD='0':

After that it checks the HOLD bit. If HOLD='0', it branches to the next transmit descriptor. Otherwise the corresponding DMAC transmit channel is deactivated as long as the host CPU does not request reactivation via the GCMR register (either transmit poll request or action request with 'IDT' command).

GMODE.CMOD='1':

After that it checks if the first (current) transmit descriptor address (LTDA) is equal to the last transmit descriptor address (LTDA) stored in the corresponding channel specific on-chip registers. When both addresses differ, it branches to the next transmit descriptor. Otherwise the corresponding DMAC transmit channel is deactivated as long as the host CPU does not write a new LTDA value to LTDA register or provides an action request with 'IDT' command.

HOLD: Hold (only valid when GMODE.CMODE=0)

It indicates whether the current descriptor is the last element of a linked list or not:

HOLD='0':

A next descriptor is available in the shared memory; after checking the HOLD bit stored in the on-chip memory the DMAC branches to next transmit descriptor.

HOLD='1':

The current descriptor is the last one that is available for the DMAC. The corresponding DMAC channel is deactivated for transmit direction as long as the microprocessor does not request an activation via the CMDR register.

NO: Byte Number

This byte number defines the number of bytes stored in the data section to be transmitted. Thus the maximum length of data buffer is 8191 bytes (i.e. NO = 0x1FFF). A transmit descriptor and the corresponding data section must contain at least either one data byte or a frame end indication. Otherwise a DMA controller interrupt with 'ERR' bit set is generated.

HI: Host Initiated Interrupt

If the HI bit is set, the corresponding DMAC generates an interrupt with set HI bit after transferring all data bytes of the current data section.

Next Transmit Descriptor Pointer:

This 32-bit pointer contains the start address of the next transmit descriptor. After sending the indicated number of data bytes, the DMAC branches to the next transmit descriptor to continue transmission. The transmit descriptor is read entirely at the beginning of transmission and stored in on-chip memory. Therefore all information in the next descriptor must be valid when the DMAC branches to this descriptor. This pointer is not used if a transmitter reset or initialization channel command is detected while the DMAC still reads data from the current transmit descriptor. In this case BTDA value in the BTDA register is used as a pointer for the next transmit descriptor to be branched to.

Transmit Data Pointer:

This 32-bit pointer contains the start address of the transmit data section. Although the TCP863 works long word oriented, it is possible to begin transmit data section at byte addresses.

C: Complete

This bit is set by the DMAC if

- it completes reading data section normally
- it was aborted by a transmitter reset command.

3.1.2 DMAC Receive Descriptor Lists

Each receive descriptor consists of 5 consecutive DWORDs located DWORD aligned in the shared memory. The first 3 DWORDs are read by the corresponding DMA channel using a burst transaction and provide information about the next descriptor in the linked list, the attached receive data buffer and its size, as well as some control bits.

The fourth DWORD is written by the DMA channel indicating that operation on this descriptor is finished. The fifth DWORD is also written by the DMA channel but only in descriptors containing the first or only data section of an HDLC frame or data block. It is a pointer to the last descriptor containing the frame or block end ('FE' bit) allowing the software to unchain the complete partial descriptor list containing one frame or block without parsing through the list for 'FE' indication.

The CPU will write the address of the first descriptor of each linked list to a dedicated Base Address Register during initialization procedure. The corresponding DMA channels start operating the linked lists at these addresses.

3.1.2.1 Receive Descriptor

DWORD	31	30	29	28..16	15..8	7..0
0	0	HOLD	HI	NO	0	
1	Next Receive Descriptor Pointer					
2	Receive Data Pointer					
3	FE	C	0	BNO	STATUS	0
4	Frame End Descriptor Pointer					

Figure 3-3 : Receive Descriptor

HOLD: Hold (only valid when GMODE.CMODE=0)

It indicates whether the current descriptor is the last element of a linked list or not:

HOLD='0':

A next descriptor is available in the shared memory; after checking the HOLD bit stored in the on-chip memory the DMAC branches to next receive descriptor

HOLD='1':

The current descriptor is the last one that is available for the DMAC. After completion of the current receive descriptor an interrupt is generated and the corresponding DMAC channel is deactivated for receive direction as long as the microprocessor does not request an activation via the CMDR register.

HI: Host Initiated Interrupt

If the HI bit is set, the corresponding DMAC generates an interrupt with set HI bit after transferring all data bytes into the current data section.

NO: Byte Number

This byte number defines the size of the receive data section allocated by the host. It has to be a multiple of 4 bytes which is responsibility of the software. The maximum buffer length is 8188 bytes (i.e. NO = 0x1FFC).

Next Receive Descriptor Pointer:

This 32-bit pointer contains the start address of the next receive descriptor. After completing the current receive descriptor the DMAC branches to the next receive descriptor to continue reception. The receive descriptor is read entirely at the beginning of reception and stored in on-chip memory. Therefore all information in the next descriptor must be valid when the DMAC branches to this descriptor.

Receive Data Pointer:

This 32-bit pointer contains the start address of the receive data section. The start address must be DWORD aligned.

FE: Frame End

It indicates that the current receive data section (addressed by Receive Data Pointer) contains the end of a frame (HDLC) or the end of data block (ASYNC). This bit is set by the DMAC after transferring the last data from the internal FIFO into the receive data section. Moreover the BNO and STATUS is updated and the 'C' bit is set by the DMAC.

GMODE.CMODE='0':

After that it checks the HOLD bit stored in the on-chip memory. If HOLD='0', it branches to the next receive descriptor. Otherwise the corresponding DMAC receive channel is deactivated as long as the host CPU does not request reactivation via the GCMR register (action request with 'IDR' command).

GMODE.CMODE='1':

After that it checks if the first (current) receive descriptor address (LRDA) is equal to the last receive descriptor address (LRDA) stored in the corresponding channel specific on-chip registers. When both addresses differ, it branches to the next receive descriptor. Otherwise the corresponding DMAC receive channel is deactivated as long as the host CPU does not write a new LRDA value to LRDA register or provides an action request with 'IDR' command.

C: Complete

This bit is set by the DMAC if:

- it completed filling data section normally
- it was aborted by a receiver reset command
- end of frame (HDLC) or end of block (ASYNC) was stored in the receive data section.

BNO: Byte Number of Received Data

DMAC writes the number of data bytes that were stored in the current data section into BNO.

Frame End Descriptor Pointer:

This 32-bit pointer is only valid in the descriptor, which contains the data pointer to the first data section of an HDLC frame or ASYNC block. This pointer is updated by the DMAC with the address of the descriptor that contains the data pointer to the last section (FE) of the HDLC frame or ASYNC block.

Receive descriptor STATUS bit field:

7	6	5	4	3	2	1	0
0	0	0	0	0	0	RA	0

RA: Receive Abort

This bit indicates that the reception of a frame (HDLC) or block (ASYNC) was ended by a DMA receiver reset command or by a HOLD bit in the current receive descriptor or by a FRDA=LRDA condition.

3.1.2.2 Receive Data Section Status Byte (HDLC Mode)

In HDLC protocol mode, the last byte of a frame (Receive Status Byte, RSTA) - located in the data section - contains error indications caused by the SCC (e.g. CRC, receive abort, ...).

RSTA:

7	6	5	4	3	2	1	0
1	RFO	CRC	RAB	0	0	0	0

The contents of the RSTA byte relates to the received HDLC frame and is generated when end-of-frame is recognized at the serial receive interface. Bit 7 is always '1' for compatibility with TCP862.

RFO: Receive FIFO Overflow

A data overflow has occurred during reception of the frame. Additionally, an interrupt can be generated (refer to ISR.RFO / IMR.RFO).

CRC: CRC Compare/Check

0: CRC check failed, received frame contains errors.

1: CRC check OK, no errors detected in received frame.

RAB: Receive Message Aborted

The received frame was aborted from the transmitting station. According to the HDLC protocol, this frame must be discarded by the receiver station.

3.1.2.3 Receive Data Section Status Byte (ASYNC Modes)

In ASYNC protocol mode a status byte can be attached additionally to every stored data byte (CCR2.RFDF='1').

The data character and status character format is determined as follows:

15	14	13..9	8	7..0
parity error	frame error	reserved	parity bit	data byte

3.2 DMAC Interrupt Controller

The interrupt concept is based on 32-bit interrupt vectors generated by the different blocks. Interrupt vectors are stored in an interrupt FIFO which is 32 DWORDs deep. The interrupt controller transfers available vectors to one of nine circular interrupt queues located in the shared memory depending on the source ID of each interrupt vector.

In addition new interrupt vectors are indicated in the global status register GSTAR on a per queue basis and selectively confirmed by writing '1' to the corresponding GSTAR bit positions. The PCI interrupt signal INTA is asserted with any new interrupt event and remains asserted until all events are confirmed.

Each interrupt queue length and memory location can be configured via specific interrupt queue base address registers and two shared interrupt queue length registers. The queue length is individually programmable in multiples of 32 DWORDs (see IQLENR0/1).

One dedicated interrupt queue is provided per SCC channel and direction (IQSCCiRX and IQSCCiTX). Non channel specific interrupt vectors generated by the DMAC itself are transferred to the configuration queue IQCFG.

The internal blocks provide mask registers for suppressing interrupt indications. Masked interrupts will neither generate an interrupt vector nor an INTA signal and GSTAR indication.

The DMA interrupt controller generates 6 channel specific interrupts regarding transmit and receive descriptor handling:

Host Initiated interrupt (HI):

This interrupt can be forced by setting bit 'HI' in the receive and transmit descriptor. In this case the DMAC will generate an HI-interrupt with completion of this descriptor i.e. when the DMAC is ready to branch to the next descriptor address. This might be used to monitor the progress of the corresponding DMA channel on the descriptor list. As an example the HI interrupt can be used to dynamically request attachment of new receive descriptors to the list if the DMA channel comes close to the list end.

Frame Indication interrupt (FI):

This interrupt is generated with completion of any receive and transmit descriptor with a set 'frame end/block end' indication, i.e. FE='1'.

Error interrupt (ERR):

Indicates an unexpected descriptor configuration

Receive descriptor:

ERR is generated if receive data cannot be transferred to the shared memory completely because the frame (block) does not fit into the current data section and a HOLD condition (HOLD bit or LRDA=FRDA) prevents the DMAC from branching to the next descriptor.

ERR is also generated if an already started DMA transfer is aborted by a receive DMA reset (RDR) command.

Transmit descriptor:

In transmit direction an ERR interrupt is generated if one of the following descriptor settings is detected

- HOLD='1' and FE='0' (the already started transmit frame could not be finished)
- LTDA=FTDA and FE='0' (the already started transmit frame could not be finished)
- FE='0' and NO='0' (a packet of length 0 is supposed to be a 'frame' with FE bit set)

The DMA controller will continue 'normal' operation in case of an ERR event. Nevertheless these cases may result in receive data overflows or transmit data underruns.

FI and HI interrupt indications caused by one descriptor will be generated into one interrupt vector with 'HI' and 'FI' bit set.

3.2.1 Interrupt Vector Description

3.2.1.1 Configuration Interrupt Vector

Configuration interrupt vectors are transferred to Configuration Interrupt Queue 'IQCFG'.

31..28	27..2	1	0
Source ID = 1010	0	ARF	ARACK

Figure 3-4 : Configuration Interrupt Vector

ARF: Action Request Failed Interrupt

This bit indicates that an action request command was completed with an 'action request failed' condition:

ARF='0': No action request was performed or no 'action request failed' condition occurred completing an action request.

ARF='1': The last action request command was completed with an 'action request failed' condition.

ARACK: Action Request Acknowledge Interrupt

This bit indicates that an action request command was completed successfully:

ARACK='0': No action request was performed or completed successfully.

ARACK='1': The last action request command was completed successfully.

3.2.1.2 DMA Controller Interrupt Vector

DMA controller interrupt vectors are transferred to the corresponding channel and direction specific interrupt queues IQSCCiRX and IQSCCiTX respectively.

31	30..28	27..19	18	17	16	15..0

Figure 3-5 : DMA Controller Interrupt Vector

Source ID: 000 Receive Channel 0 Interrupt Vector (IQSCC0RX)

001 Receive Channel 1 Interrupt Vector (IQSCC1RX)

010 Receive Channel 2 Interrupt Vector (IQSCC2RX)

011 Receive Channel 3 Interrupt Vector (IQSCC3RX)

100 Transmit Channel 0 Interrupt Vector (IQSCC0TX)

101 Transmit Channel 1 Interrupt Vector (IQSCC1TX)

110 Transmit Channel 2 Interrupt Vector (IQSCC2TX)

111 Transmit Channel 3 Interrupt Vector (IQSCC3TX)

HI: Host Initiated interrupt (Rx/Tx Channel)

This bit indicates that a Host Initiated (HI) interrupt occurred, i.e. the corresponding DMA controller channel detects the 'HI' bit set to '1' in the receive or transmit descriptor before branching to the next descriptor.

HI='0' No Host Initiated (HI) interrupt is indicated by this vector.

HI='1' A Host Initiated (HI) interrupt is indicated by this vector.

FI: Frame Indication interrupt (Rx/Tx Channel)

This bit indicates that a Frame Indication (FI) interrupt occurred.

Receive direction:

FI='1' indicates, that a frame has been received completely or was stopped by a DMAC receiver reset command or a hold condition set in a receive descriptor. It is set when the DMAC branches from the last descriptor belonging to the current frame (or block) (FE='1') to the first descriptor of a new frame. It is also set when the descriptor in which the frame/block is finished contains a hold condition.

Transmit direction:

Issued if the 'FE' bit is detected in the transmit descriptor. It is set when the DMAC branches to the next transmit descriptor, belonging to a new frame or when 'HOLD' bit is set in conjunction with 'FE' bit. Only 'ERR' indication without 'FI' is set, if a transmit descriptor contains a 'HOLD' (hold condition) but no 'FE' bit.

FI='0' No Frame Indication (FI) interrupt is indicated by this vector.

FI='1' A Frame Indication (FI) interrupt is indicated by this vector.

ERR: ERROR Indication interrupt (Rx/Tx Channel)

This bit indicates that an Error interrupt occurred.

Receive direction:

Issued if the current frame/block could not be transferred to the shared memory completely, because of a hold condition in a receive descriptor not providing enough bytes for the frame/block or the frame/block was aborted by a DMAC receiver reset command.

Transmit direction:

Issued if a transmit descriptor contains a hold condition but FE='0' or if the last descriptor had NO=0 and FE='0'.

ERR='0' No Error (ERR) interrupt is indicated by this vector.

ERR='1' An Error (ERR) interrupt is indicated by this vector.

3.2.1.3 SCC Interrupt Vector

Serial Channel (SCC) related interrupt vectors are transferred to the corresponding channel and direction specific interrupt queues IQSCCiRX and IQSCCiTX respectively.

Interrupt vectors generated by the SCCs might contain interrupt indications for both, receive AND transmit direction. But in receive interrupt queues only the receive interrupt indications need to be served and in transmit interrupt queues only transmit interrupt indications need to be served by the software.

Source ID: 000 Receive Channel 0 Interrupt Vector (IQSCC0RX)

001 Receive Channel 1 Interrupt Vector (IQSCC1RX)

010 Receive Channel 2 Interrupt Vector (IQSCC2RX)

011 Receive Channel 3 Interrupt Vector (IQSCC3RX)

100 Transmit Channel 0 Interrupt Vector (IQSCC0TX)

101 Transmit Channel 1 Interrupt Vector (IQSCC1TX)

110 Transmit Channel 2 Interrupt Vector (IQSCC2TX)

111 Transmit Channel 3 Interrupt Vector (IQSCC3TX)

Bit field 18..0 of the SCC interrupt vector is a copy of the SCC Interrupt Status Register ISR (for detailed information see chapter 'ISR - Interrupt Status Register').

4 Serial Communication Controller

4.1 Protocol Description

The following table provides an overview of all supported protocol modes and their assignment to the major protocol engines HDLC and ASYNC. The protocol engine of each SCC is selected via bit field 'SM' in register CCR0. The HDLC Sub Modes are selected via additional bit fields in registers CCR0 and CCR1.

Protocol Engine:	Protocol Mode:	
Register CCR0 Setting:		Register CCR1 Setting (bit fields MDS):
HDLC SM = '00'	HDLC address mode 0	MDS = '10'
	Extended transparent mode	MDS = '11'
		Register CCR0 Setting (bit BCR):
ASYNC SM = '11'	Asynchronous mode	BCR = '1'
	Isochronous mode	BCR = '0'

Figure 4-1 : Protocol Modes

Extended transparent is a fully bit-transparent transmit/reception mode which is treated as a sub-mode of the HDLC block.

4.1.1 HDLC Mode

4.1.1.1 Address Mode 0

Standard HDLC framing is performed and each complete frame will be stored in the receive FIFO, optional CRC generation/check.

Figure 4-2 : Address Mode 0

4.1.1.2 Extended Transparent Mode

In extended transparent mode, fully transparent data transmission/reception without HDLC framing is performed, i.e. without FLAG generation/recognition, CRC generation/check, or bit stuffing. This allows user specific protocol variations.

4.1.2 Asynchronous (ASYNC) Mode

Character framing is achieved by start and stop bits. Each data character is preceded by one start bit and terminated by one or two stop bits. The character length is selectable from 5 up to 8 bits. Optionally, a parity bit can be added which complements the number of ones to an even or odd quantity (even/odd parity). The parity bit can also be programmed to have a fixed value (Mark or Space). The character format configuration is performed via appropriate bit fields in register CCR2.

4.1.2.1 Asynchronous Mode

Bit clock rate 16 is selected (register CCR0, bit BCR = '1'), NRZ data encoding should be selected (register CCR0, bit field 'SC').

The receiver operates at a clock rate which is 16 times the nominal (expected) data bit rate. It synchronizes itself to each character by detecting and verifying the start bit. Oversampling (3 samples) around the nominal bit center in conjunction with majority decision is provided for every received bit (including start bit).

The synchronization lasts for one character; the next incoming character causes a new synchronization. As a result, the demand for high clock accuracy is reduced. Two communication stations using the asynchronous procedure are clocked independently; their clocks need not to be in phase or locked to exactly the same frequency but, in fact, may differ from one another within a certain range.

4.1.2.2 Isochronous Mode

Bit clock rate 1 is selected (register CCR0 bit BCR = '0').

The isochronous mode uses the asynchronous character format. However, each data bit is only sampled once (no oversampling). The input clock has to be externally phase locked to the data stream. This mode allows much higher transfer rates.

4.1.2.3 Storage of Receive Data

If the receiver is enabled, received data is stored in the receive FIFO (the LSB is received first). Character length, number of stop bits and the optional parity bit are checked. Errors are indicated via interrupts. Additionally, the character specific error status (framing and parity) can optionally be stored in the receive FIFO. Filling of the receive FIFO is controlled by

- a programmable threshold level (bit field 'RFTH' in register CCR2),
- the selected data format (bit 'RFDF' in register CCR2),
- detection of the programmable Termination Character (bit 'TCDE' and bit field 'TC' in register TCR).

Additionally, the time-out event interrupt as an optional status information indicates that a certain time (refer to register CCR1) has elapsed since the reception of the last character.

4.1.2.4 Data Transmission

The selection of asynchronous or isochronous operation has no further influence on the transmitter. The bit clock rate is solely a dividing factor for the selected clock source.

Transmission of the contents of the transmit FIFO starts after providing data to the DMA controller. The character frame for each character, consisting of start bit, the character itself with defined character length, optionally generated parity bit and stop bit(s) is assembled.

After finishing transmission (indicated by the 'ALLS' interrupt), IDLE sequence (logical '1') is transmitted on transmit pin TxD.

Additionally, the CTS signal may be used to control data transmission.

4.1.2.5 Break Detection/Generation

Break generation:

On issuing the transmit break command (bit 'XBRK' in register CCR2), the TxD pin is immediately forced to physical '0' level with the next following clock edge, and released with the first clock edge after this command is reset again by software.

Break detection:

The SCC recognizes the break condition upon receiving consecutive (physical) '0's for the defined character length, the optional parity and the selected number of stop bits ('zero' character and framing error). The 'zero' character is not pushed to RFIFO. The 'Break' interrupt (BRK) is generated, if enabled. The break condition will be present until a '1' is received which is indicated by the 'Break Terminated' interrupt (BRKT).

4.1.2.6 Flow Control

Transmitter:

The transmitter output is enabled if CTS signal is 'LOW'. Setting bit CCR1.FCTS = '1' allows the transmitter to send data independent of the condition of the CTS signal.

Receiver:

For some applications it is desirable to provide means of flow control to indicate to the far end transmitter that the local receiver's buffer is getting full.

This flow control can be used between two DTEs and between a DTE and a DCE (MODEM) that supports this kind of bi-directional flow control.

Setting bit CCR1.FRTS = '1' and CCR1.RTS = '0' invokes the flow control for the receiver. When the SCC receive FIFO has reached a threshold of 12 bytes (16 bytes total), the RTS signal is forced inactive (HIGH). When the receive FIFO is nearly empty (2 bytes), the RTS is re-asserted ('LOW'). Note that data is immediately transferred from the SCC receive FIFO to the DMA accessible FIFO (as long as there is space available). Thus when the SCC receive FIFO reaches the 12 bytes threshold, there are 4 more bytes storage available before an overflow can occur. This provides sufficient time for the far end transmitter to react to the change in the RTS signal and stop sending more data.

4.2 Clock Sources

The TCP863 has several clock sources for transmitter and receiver controlled by the ACR. Possible sources are the three on-board oscillators (14.7456 MHz, 24 MHz and 10 MHz), the external RxCLK and TxCLK inputs. TxCLK can be an input for the internal transmit clock or an output for transmit clock monitor signal (see following figure).

The guaranteed maximum data rate is limited by the multiprotocol transceivers and is at least 10Mbit/s in EIA-530 (V.11) and V.35 transceiver modes. Maximum data rate of EIA-232 (V.28) is 115.2kbit/s. (see datasheets of transceivers, e.g. in the TCP863-ED). The maximum data rate in asynchronous mode with oversampling or DPLL mode is 2 Mbit/s. To generate higher internal clock frequencies for oversampling or DPLL reference clock, an optional x4 clock multiplier can be used.

The input frequency range of the x4 clock multiplier is 4.5 MHz to 28 MHz, these values must never be exceeded to ensure proper function of the clock multiplier.

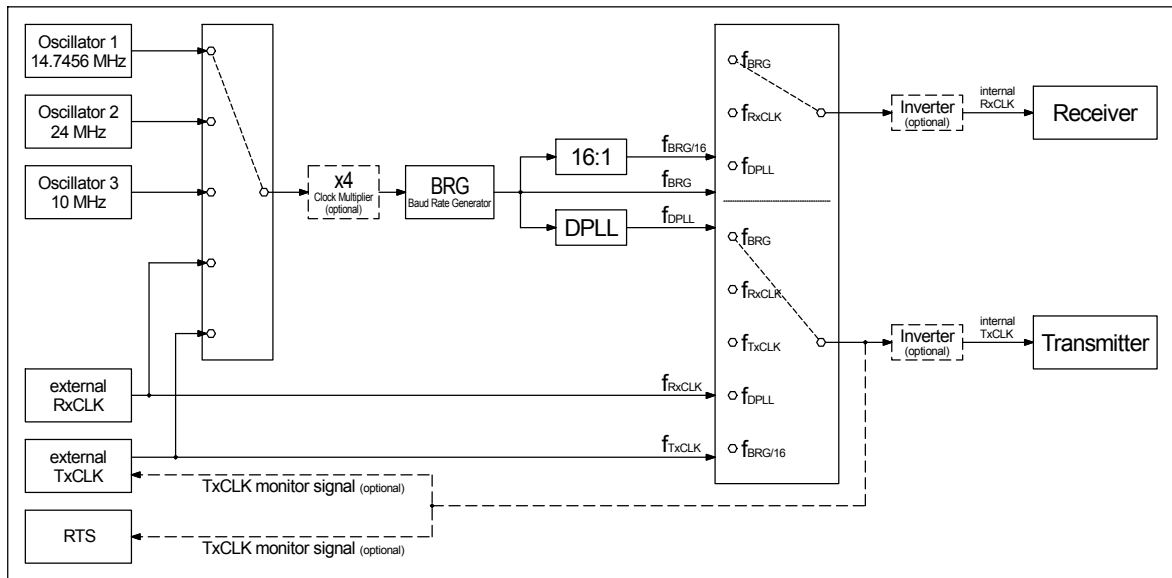

Figure 4-3 : Clock Sources

4.3 Baud Rate Generation

Each of the four channels has its own Baud Rate Generator (BRG). They are controlled by registers BRR (0x012C, 0x01AC, 0x022C, 0x02AC).

The Baud Rate Generator Frequency is: $f_{BRG} = f_{in} / k$.

The baud rate generator input clock f_{in} depends on the selected clock source (see also previous chapter "Clock Sources").

The divisor k can be set in 2 ways, determined by BRR[31]. When BRR[31] = 0, k is calculated the former way as with the TCP862:

$$k = (N + 1) \times 2^M$$

with N (BRR[5:0]) = 0..63 and M (BRR[11:8]) = 0..15

The alternative is to set k directly as a 21-bit wide value, when BRR[31] = 1.

When asynchronous mode is selected (register CCR0, bit BCR = '1'), k is multiplied by 16.

4.4 Data Encoding

The following codings of the serial data are supported:

- Non-Return-To-Zero (NRZ)
- Non-Return-To-Zero-Inverted (NRZI)
- FM0 (known as Bi-Phase Space)
- FM1 (known as Bi-Phase Mark)
- Manchester (known as Bi-Phase)

4.4.1 NRZ and NRZI Encoding

NRZ: The signal level corresponds to the value of the data bit.

NRZI: A logical '0' is indicated by a transition and a logical '1' by no transition at the beginning of the bit cell.

Figure 4-4 : NRZ and NRZI Data Encoding

4.4.2 FM0 and FM1 Encoding

FM0: An edge occurs at the beginning of every bit cell. A logical '0' has an additional edge in the center of the bit cell, whereas a logical '1' has none. The transmit clock precedes the receive clock by 90°.

FM1: An edge occurs at the beginning of every bit cell. A logical '1' has an additional edge in the center of the bit cell, a logical '0' has none. The transmit clock precedes the receive clock by 90°.

Figure 4-5 : FM0 and FM1 Data Encoding

4.4.3 Manchester Encoding

In the first half of the bit cell, the physical signal level corresponds to the logical value of the data bit. At the center of the bit cell this level is inverted. The transmit clock precedes the receive clock by 90°.

Figure 4-6 : Manchester Data Encoding

4.5 Clock Recovery (DPLL)

The SCC offers the advantage of recovering the received clock from the received data by means of internal DPLL circuitry, eliminating the need to transfer additional clock information via a separate serial clock line. For this purpose, the DPLL is supplied with a 'reference clock' from the BRG which is 16 times the expected data clock rate. The transmit clock may be obtained by dividing the output of the BRG by a constant factor of 16 or also directly from the DPLL (see 'TCS' in register ACR).

The main task of the DPLL is to derive a receive clock and to adjust its phase to the incoming data stream in order to enable optimal bit sampling.

The mechanism for clock recovery depends on the selected data encoding (see chapter "Data Encoding").

Figure 6-2 : Global Registers

6.3 SCC Registers Overview

Each SCC register space (see table “Local Register Space”) contains the following registers:

The SCC registers are used to configure and control each of the four Serial Communication Controllers (SCC). The complete SCC register set exists four times, i.e. one for each SCC, distinguished by a SCC specific offset address.

The full 32 bit address location of each SCC register consists of:

- Base Address Register 0 (PCI Configuration Space, address location 0x10)
- SCC specific offset address:

SCC0: 0x0100

SCC1: 0x0180

SCC2: 0x0200

SCC3: 0x0280

- Register address offset, which is in the range 0x00 ...0x58

Most registers and register bit positions are shared by all SCC protocol modes (HDLC, ASYNC). Nevertheless the meaning (and name) of single bit positions might defer between different protocol modes. All registers are 32-bit organized registers.

Offset to Base Address 0x0100 (SCC0) 0x0180 (SCC1) 0x0200 (SCC2) 0x0280 (SCC3)	Register Name

6.4 Global Registers

Basic function of register bits is the same as for the high speed serial controller used on the TCP862.

6.4.1 GCMDR – Global Command Register (0x0000)

Bit	Symbol	Description	Access	Reset Value
31	CFGIQSCC3RX	Configure Interrupt Queue SCC3 Receive Only valid, if action request bit 'AR' is set. The DMA (interrupt) controller will transfer interrupt vectors generated by the dedicated SCC receiver (3..0) to the corresponding interrupt queue which must be configured via 'CFGIQSCCiRX' command bits: '0': The DMA (interrupt) controller does NOT configure/re-configure the corresponding interrupt queue, if action request bit 'AR' is set to '1'. '1': Causes the DMA (interrupt) controller to configure/re-configure the corresponding interrupt queue, if action request bit 'AR' is set to '1'. On action request, the DMA (interrupt) controller will evaluate the corresponding interrupt queue base address and length registers which must have been programmed by software before.	R/W	0
30	CFGIQSCC2RX	Configure Interrupt Queue SCC2 Receive (see above)	R/W	0
29	CFGIQSCC1RX	Configure Interrupt Queue SCC1 Receive (see above)	R/W	0
28	CFGIQSCC0RX	Configure Interrupt Queue SCC0 Receive (see above)	R/W	0

Bit	Symbol	Description	Access	Reset Value
27	CFGIQSCC3TX	Configure Interrupt Queue SCC3 Transmit Only valid, if action request bit 'AR' is set. The DMA (interrupt) controller will transfer interrupt vectors generated by the dedicated SCC transmitter (3..0) to the corresponding interrupt queue which must be configured via 'CFGIQSCCiTX' command bits: '0': The DMA (interrupt) controller does NOT configure/re-configure the corresponding interrupt queue, if action request bit 'AR' is set to '1'. '1': Causes the DMA (interrupt) controller to configure the corresponding interrupt queue, if action request bit 'AR' is set to '1'. On action request, the DMA (interrupt) controller will evaluate the corresponding interrupt queue base address and length registers which must have been programmed by software before.	R/W	0
26	CFGIQSCC2TX	Configure Interrupt Queue SCC2 Transmit (see above)	R/W	0
25	CFGIQSCC1TX	Configure Interrupt Queue SCC1 Transmit (see above)	R/W	0
24	CFGIQSCC0TX	Configure Interrupt Queue SCC0 Transmit (see above)	R/W	0
23:22	-	Reserved (0 for reads)	R	0
21	CFGIQCFG	Configure Interrupt Queue Configuration Only valid, if action request bit 'AR' is set. The DMA (interrupt) controller will transfer action request acknowledge/failure interrupt vectors to the configuration interrupt queue which must be configured via 'CFGIQCFG' command bits: '0': The DMA (interrupt) controller does NOT configure/re-configure the configuration interrupt queue, if action request bit 'AR' is set to '1'. '1': Causes the DMA (interrupt) controller to configure the configuration interrupt queue, if action request bit 'AR' is set to '1'. On action request, the DMA (interrupt) controller will evaluate the configuration interrupt queue base address and length registers which must have been programmed by software before.	R/W	0
20:14	-	Reserved (0 for reads)	R	0

Bit	Symbol	Description	Access	Reset Value
13	TXPR3	<p>Transmit Poll Request Channel 3</p> <p>Self-clearing command bit, only valid in 'HOLD' bit controlled DMA controller mode (bit CMODE = '0' in register GMODE):</p> <p>'0': No Transmit Poll Request is performed. The corresponding DMA controller transmit channel is stopped when HOLD='1' has been detected in the current transmit descriptor.</p> <p>'1': Setting this bit to '1', when HOLD='1' has been detected in the current transmit descriptor, will cause the controller to poll the 'HOLD' bit in the current transmit descriptor, i.e. the controller reads the configuration word (DWORD 0) and next descriptor address (DWORD 1) of the current descriptor again. If the 'HOLD' bit is detected cleared ('0'), the DMA controller will branch to the next descriptor.</p> <p>When the DMA controller is not in 'HOLD' state, this command is discarded.</p>	R/W	0
12	TXPR2	Transmit Poll Request Channel 2	R/W	0
11	TXPR1	Transmit Poll Request Channel 1	R/W	0
10	TXPR0	Transmit Poll Request Channel 0	R/W	0
9	IMAR	Interrupt Mask Action Request	R/W	1
8:1	-	Reserved (0 for reads)	R	0
0	AR	Action Request	R/W	0

Figure 6-4 : Global Command Register

6.4.2 GSTAR – Global Status Register (0x0004)

Written by DMA Controller as interrupt indication

The Global Status Register indicates whether an action request was executed successfully or not. It also gives information about the interrupt source and which interrupt queue has been written to when INTA# is activated.

Nine interrupt queues are provided:

- four queues for receive interrupt vectors of the SCCs (SCCi, i=0...3)
- four queues for transmit interrupt vectors of the SCCs (SCCi, i=0...3)
- one queue for configuration interrupt vectors (action request acknowledge/failed)

To clear any bit in the status register, the host CPU must set the corresponding bit to '1' by register write access. Signal INTA# will be deasserted by the TCP863 if all GSTAR Interrupt Indication bits are cleared.

Bit	Symbol	Description	Access	Reset Value
31	IISCC3RX	Interrupt Indication Queue SCC3 Receive	R/C	0
30	IISCC2RX	Interrupt Indication Queue SCC2 Receive	R/C	0
29	IISCC1RX	Interrupt Indication Queue SCC1 Receive	R/C	0
28	IISCC0RX	Interrupt Indication Queue SCC0 Receive These bits indicate whether at least one new interrupt vector was transferred into the corresponding receive interrupt queue: '0': No new interrupt vector was transferred into the corresponding queue. '1': At least one new interrupt vector was transferred into the corresponding queue.	R/C	0
27	IISCC3TX	Interrupt Indication Queue SCC3 Transmit	R/C	0
26	IISCC2TX	Interrupt Indication Queue SCC2 Transmit	R/C	0
25	IISCC1TX	Interrupt Indication Queue SCC1 Transmit	R/C	0
24	IISCC0TX	Interrupt Indication Queue SCC0 Transmit These bits indicate whether at least one new interrupt vector was transferred into the corresponding transmit interrupt queue: '0': No new interrupt vector was transferred into the corresponding queue. '1': At least one new interrupt vector was transferred into the corresponding queue.	R/C	0
23:22	-	Reserved (0 for reads)	R	0

Bit	Symbol	Description	Access	Reset Value
21	IICFG	Interrupt Indication Configuration Queue These bits indicate whether at least one new interrupt vector was transferred into the configuration interrupt queue: '0': No new interrupt vector was transferred into the corresponding queue. '1': At least one new interrupt vector was transferred into the corresponding queue.	R/C	0
20:2	-	Reserved (0 for reads)	R	0
<i>Action Request Result Status</i>				
1	ARF	Action Request Failed Status This bit indicates that an action request command was completed with an 'action request failed' condition: '0': No action request was performed or no 'action request failed' condition occurred completing an action request. '1': The last action request command was completed with an 'action request failed' condition.	R/C	0
0	ARACK	Action Request Acknowledge Status This bit indicates that an action request command was completed successfully: '0': No action request was performed or completed successfully. '1': The last action request command was completed successfully.	R/C	0

Figure 6-5 : Global Status Register

6.4.3 GMODE – Global Mode Register (0x0008)

Bit	Symbol	Description	Access	Reset Value
31:1	-	Reserved (0 for reads)	R	0
0	CMODE	DMA Control Mode '0' 'HOLD' bit control mode. The descriptor chain end condition is controlled via the 'HOLD' bit in each receive/transmit descriptor. '1' Last Receive/Transmit Descriptor Address mode. The descriptor chain end condition is controlled via registers LRDA/LTDA.	R/W	0

Figure 6-6 : Global Mode Register

6.4.4 IQLENR0 – Interrupt Queue Length Register 0 (0x000C)

Bit	Symbol	Description	Access	Reset Value
31:28	IQSCC0RXLEN	Interrupt Queue SCC3 Receive Length	R/W	0
27:24	IQSCC1RXLEN	Interrupt Queue SCC2 Receive Length	R/W	0
23:20	IQSCC2RXLEN	Interrupt Queue SCC1 Receive Length	R/W	0
19:16	IQSCC3RXLEN	Interrupt Queue SCC0 Receive Length These bit fields determine the length of the corresponding receive interrupt queue (related to the respective SCC receive channel): Queue Length = (1 + 'IQSCCiRXLEN') * 32 DWORDS 'IQSCCiRXLEN' = 0...15	R/W	0
15:12	IQSCC0TXLEN	Interrupt Queue SCC3 Transmit Length	R/W	0
11:8	IQSCC1TXLEN	Interrupt Queue SCC2 Transmit Length	R/W	0
7:4	IQSCC2TXLEN	Interrupt Queue SCC1 Transmit Length	R/W	0
3:0	IQSCC3TXLEN	Interrupt Queue SCC0 Transmit Length These bit fields determine the length of the corresponding transmit interrupt queue (related to the respective SCC transmit channel): Queue Length = (1 + 'IQSCCiTXLEN') * 32 DWORDS, 'IQSCCiTXLEN' = 0...15	R/W	0

6.4.8 FIFO CR4 – FIFO Control Register 4 (0x0034)

Bit	Symbol	Description	Access	Reset Value
31:24	TFFTHRES3	Transmit FIFO Forward Threshold Channel 3	R/W	0
23:16	TFFTHRES2	Transmit FIFO Forward Threshold Channel 2	R/W	0
15:8	TFFTHRES1	Transmit FIFO Forward Threshold Channel 1	R/W	0
7:0	TFFTHRES0	<p>Transmit FIFO Forward Threshold Channel 0</p> <p>These bit fields determine the channel specific Transmit FIFO Forward Threshold for the corresponding channel <i>i</i> in number of DWORDs. This threshold controls DMAC operation towards the serial channels (SCCi).</p> <p>As soon as the number of valid data belonging to a new frame in the central transmit FIFO is greater than the threshold, the DMAC will provide transmit data to the corresponding SCC. Once having started one frame, the DMAC will ignore this threshold providing all available data of the current frame to the SCC. Threshold operation starts again with the beginning of a new frame. Frames shorter than the threshold will be transferred as soon as a frame end indication is detected by the DMAC.</p> <p><i>Note: Programming TFFTHRES_i to zero will disable the threshold causing the DMAC to transfer all data immediately. This may be useful for not frame oriented data transmission, e.g. in ASYNC protocol mode.</i></p>	R/W	0

6.4.10 CHiCFG – Channel i Configuration Register (i=0...3) (0x0050, 0x005C, 0x0068, 0x0074)

Bit	Symbol	Description	Access	Reset Value
31:28	-	Reserved (0 for reads)	R	0
27	MRFI	Mask Receive FI Interrupt (Channel i) This bit enables/disables the receive FI interrupt indication for the DMA channel, the register is dedicated to (i=3..0): '0': FI interrupt generation is enabled for the dedicated DMA receive channel. '1': FI interrupt generation is disabled for the dedicated DMA receive channel.	R/W	0
26	MTFI	Mask Transmit FI Interrupt (Channel i) This bit enables/disables the transmit FI interrupt indication for the DMA channel, the register is dedicated to (i=3..0): '0': FI interrupt generation is enabled for the dedicated DMA transmit channel. '1': FI interrupt generation is disabled for the dedicated DMA transmit channel.	R/W	0
25	MRERR	Mask Receive ERR Interrupt (Channel i) This bit enables/disables the receive ERR interrupt indication for the DMA channel, the register is dedicated to (i=3..0): '0': ERR interrupt generation is enabled for the dedicated DMA receive channel. '1': ERR interrupt generation is disabled for the dedicated DMA receive channel.	R/W	0
24	MTERR	Mask Transmit ERR Interrupt (Channel i) This bit enables/disables the transmit ERR interrupt indication for the DMA channel, the register is dedicated to (i=3..0): '0': ERR interrupt generation is enabled for the dedicated DMA transmit channel. '1': ERR interrupt generation is disabled for the dedicated DMA transmit channel.	R/W	0
23	-	Reserved (0 for reads)	R	0
22	RDR	Reset DMA Receiver (Channel i) Self-clearing command bit. This command resets the specific DMA controller receive channel and also flushes the receive data FIFO. After reset, the respective DMA channel is in its initial state equal to the reset state after power on. The receive data FIFO will not accept any receive data until the IDR command is successfully finished.	R/W	0

Bit	Symbol	Description	Access	Reset Value
21	RDT	Reset DMA Transmitter (Channel i) Self-clearing command bit. This command resets the specific DMA controller transmit channel. After reset, the respective DMA channel is in its initial state equal to the reset state after power on.	R/W	0
20	IDR	Initialize DMA Receiver (Channel i) Self-clearing command bit. This command causes the specific DMA receive channel to fetch the base descriptor address from register CHiBRDA and to branch to the corresponding descriptor. Afterwards normal DMA operation on the receive descriptor list is performed depending on the selected DMA control mode. <i>Note: To avoid unexpected DMA controller behavior, it is recommended to apply 'IDR' command only, if the specific DMA channel is in reset state.</i>	R/W	0
19	IDT	Initialize DMA Transmitter (Channel i) Self-clearing command bit. This command causes the specific DMA transmit channel to fetch the base descriptor address from register CHiBTDA and to branch to the corresponding descriptor. Afterwards normal DMA operation on the transmit descriptor list is performed depending on the selected DMA control mode. <i>Note: To avoid unexpected DMA controller behavior, it is recommended to apply 'IDT' command only, if the specific DMA channel is in reset state.</i>	R/W	0
18:0	-	Reserved (0 for reads)	R	0

15:13	-	Reserved (0 for reads)	R	0
12	VIS	Masked Interrupts Visible '0': Masked interrupt status bits are not visible on interrupt status register (ISR) read accesses. '1': Masked interrupt status bits are visible in the ISR. To clear these interrupt flags, the host CPU must write '1' to the corresponding ISR bit. <i>Note: Masked interrupts will not generate an interrupt vector to the interrupt controller.</i>	R/W	0
11:8	-	Reserved (0 for reads)	R	0
7	BCR	Bit Clock Rate Only valid in asynchronous mode. '0': Isochronous (Bit Clock Rate x1). Bits are sampled once. '1': Standard asynchronous (Bit Clock Rate x16). Bits are sampled 16 times. The result is determined by a majority decision of 3 samples around the bit center. NRZ encoding has to be selected.	R/W	0
6	-	Reserved (0 for reads)	R	0
5	TOE	Transmit Clock Out Enable '0': TxC is input (DCE mode) '1': TxC is output (DTE# mode) <i>Note: The Transceiver direction of TxC is set according to TOE.</i>	R/W	0
4:0	-	Reserved (0 for reads)	R	0

Figure 6-24: Channel Configuration Register 0

6.5.4 CCR1 – Channel Configuration Register 1 (0x010C, 0x018C, 0x020C, 0x028C)

Bit	Symbol	Description	Access	Reset Value															
31:21	-	Reserved (0 for reads)	R	0															
20	RTS	Request To Send pin control (async./isochr.) The request to send pin RTS# can be controlled as an output autonomously or via setting/clearing bit 'RTS'. '0': Pin RTS# (output) is controlled autonomously. The behavior of this pin depends on bit 'FRTS'. '1': Pin RTS# can be controlled by software. The output level of this pin depends on bit 'FRTS'.	R/W	0															
19	FRTS	Flow Control (RTS) Function of RTS# depends on 'RTS' and 'FRTS'. <table border="1" style="margin-left: 20px;"> <thead> <tr> <th>FRTS</th> <th>RTS</th> <th></th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Pin RTS# is controlled autonomously. RTS is asserted (low) when data is available in the transmit FIFO.</td> </tr> <tr> <td>1</td> <td>0</td> <td>Pin RTS# is controlled autonomously. RTS is asserted (low) if the SCC receive FIFO is nearly empty (2 bytes) and de-asserted (high) if the receive FIFO fill level reaches 12 bytes.</td> </tr> <tr> <td>0</td> <td>1</td> <td>Forces RTS# to low (asserted).</td> </tr> <tr> <td>1</td> <td>1</td> <td>Forces RTS# to high (de-asserted).</td> </tr> </tbody> </table> <p><i>Note: A transmit clock is necessary. In HDLC mode the RTS pin is always controlled by software.</i></p>	FRTS	RTS		0	0	Pin RTS# is controlled autonomously. RTS is asserted (low) when data is available in the transmit FIFO.	1	0	Pin RTS# is controlled autonomously. RTS is asserted (low) if the SCC receive FIFO is nearly empty (2 bytes) and de-asserted (high) if the receive FIFO fill level reaches 12 bytes.	0	1	Forces RTS# to low (asserted).	1	1	Forces RTS# to high (de-asserted).	R/W	0
FRTS	RTS																		
0	0	Pin RTS# is controlled autonomously. RTS is asserted (low) when data is available in the transmit FIFO.																	
1	0	Pin RTS# is controlled autonomously. RTS is asserted (low) if the SCC receive FIFO is nearly empty (2 bytes) and de-asserted (high) if the receive FIFO fill level reaches 12 bytes.																	
0	1	Forces RTS# to low (asserted).																	
1	1	Forces RTS# to high (de-asserted).																	
18	FCTS	Flow Control (CTS) (async./isochr.) '0': Transmitter is stopped, if CTS# input signal is inactive (high) and enabled if asserted (low). In ASYNC mode, the current byte is completely sent even if CTS# becomes inactive during transmission. '1': Transmitter is always enabled. <i>Note: In ASYNC mode the current byte is completely sent, even if CTS# becomes deasserted during transmission.</i>	R/W	0															
17:16	-	Reserved (0 for reads)	R	0															

Bit	Symbol	Description	Access	Reset Value
15:14	MDS	Mode Select (hdlc) Selects the HDLC sub mode. '00': reserved '01': reserved '10': Address Mode 0 '11': Extended transparent mode (bit transparent transmission/reception)	R/W	00
13:9	-	Reserved (0 for reads)	R	0
8	TLP	Test Loop The test loop is closed at the far end of serial transmit and receive line just before the respective TxD and RxD pins: '0': Test loop disabled. '1': Test loop enabled.	R/W	0
7	TOIE	Time Out Indication Enable (async./isochr.) A 'block end' indication is inserted in the receive FIFO if a time out occurs. The current receive descriptor will be finished. '0': Time Out function disabled. '1': Time Out function enabled. <i>Note: A time out event will generate a 'TIME' interrupt (if unmasked).</i>	R/W	0
6:0 (asyn)	TOLEN	Time Out Length (async./isochr.) Determines the time out period. If there is no receive line activity for the configured period of time, a time out indication is generated if enabled via bit 'TOIE'. The period of time is programmable in multiples of a single character frame length (CFL) time equivalents including start, parity and stop bits: $T_{\text{TOUIT}} = (\text{TOLEN} + 1) * 1 * \text{CFL}$	R/W	0
1 (hdlc)	CRL	CRC Reset Value (hdlc) Defines the initial value of the CRC generators: '0': Initial value is 0xFFFF (16 bit CRC), 0xFFFFFFFF (32 bit CRC); (default value for most HDLC applications) '1': Initial value is 0x0000 (16 bit CRC), 0x00000000 (32 bit CRC).	R/W	0

0 (hdlc)	C32	CRC-32 Select (hdlc) This bit enables 32-bit CRC operation for transmit and receive. '0': 16-bit CRC generation/checking. '1': 32-bit CRC generation/checking.	R/W	0
-------------	-----	--	-----	---

Figure 6-25: Channel Configuration Register 1

6.5.5 CCR2 – Channel Configuration Register 2 (0x0110, 0x0190, 0x0210, 0x0290)

Bit	Symbol	Description	Access	Reset Value
31:30	-	Reserved (0 for reads)	R	0
29:28 (asyn.)	CHL	Character Length (asynch./isochr.) '00': 8 bit data '01': 7 bit data '10': 6 bit data '11': 5 bit data	R/W	00
27	RAC	Receiver active '0': Receiver inactive, receive line is ignored. '1': Receiver active.	R/W	0
26	-	Reserved (0 for reads)	R	0
25 (asyn.)	XBRK	Transmit Break (asynch./isochr.) '0': Normal transmit operation '1': Forces the TxD pin to 'low' level immediately (break condition), regardless of any character being currently transmitted. This command is executed immediately with the next rising edge of the transmit clock and further transmission is disabled. The currently sent character is lost. Data stored in the SCC transmit FIFO will be sent as soon as the break condition is cleared (XBRK='0'). A transmit reset command (bit 'XRES' in register CMDR) does NOT clear the break condition automatically.	R/W	0
24 (asyn.)	STOP	Stop Bit Number (asynch./isochr.) '0': 1 stop bit per character '1': 2 stop bits per character	R/W	0
23:22 (asyn.)	PAR	Parity Format (asynch./isochr.) '00': Space ('0') is inserted as parity bit '01': Odd parity '10': Even parity '11': Mark ('1') is inserted as parity bit <i>Note: The received parity bit (and parity error) is stored in the receive buffer if bit 'RFDF' = '1'.</i>	R/W	0
21 (asyn.)	PARE	Parity Enable (asynch./isochr.) '0': Parity generation/checking is disabled. '1': Parity generation/checking is enabled.	R/W	0
24:23 (hdlc)	-	Reserved (0 for reads)	R	0

Bit	Symbol	Description	Access	Reset Value										
22 (hdlc)	DRCRC	Disable Receive CRC Checking (hdlc) '0': The receiver expects a 16 or 32 bit CRC within a HDLC frame. '1': The receiver does not expect a CRC. <i>Note: A received checksum (2 or 4 bytes) is always forwarded to the receive buffer as data.</i>	R/W	0										
21 (hdlc)	-	Reserved (0 for reads)	R	0										
20	-	Reserved (0 for reads)	R	0										
19	RFDF	Receive FIFO Data Format (async./isochr.) '0': No additional status information stored. '1': Status byte is stored after each data byte to the receive buffer: <table border="1" style="margin: 10px auto;"> <tr> <td style="text-align: center;">15</td> <td style="text-align: center;">14</td> <td style="text-align: center;">13...9</td> <td style="text-align: center;">8</td> <td style="text-align: center;">7.....0</td> </tr> <tr> <td style="text-align: center;">parity error</td> <td style="text-align: center;">frame error</td> <td style="text-align: center;">reserved</td> <td style="text-align: center;">parity bit</td> <td style="text-align: center;">data byte</td> </tr> </table> <i>Note: RFDF value is only evaluated while Receiver Reset 'RRES' is active.</i>	15	14	13...9	8	7.....0	parity error	frame error	reserved	parity bit	data byte	R/W	0
15	14	13...9	8	7.....0										
parity error	frame error	reserved	parity bit	data byte										
18	RFTH	Receive FIFO Threshold '0': Maximum PCI bus write burst length for receive data is set to 15 DWORDs. '1': Maximum PCI bus write burst length for receive data is set to 1 DWORD.	R/W	0										
17:4	-	Reserved (0 for reads)	R	0										
3	ITF	Interframe Time Fill (hdlc) This bit selects the idle state of the transmit pin TxD: '0': Continuous logical '1' is sent during idle phase. '1': Continuous flag sequences are sent ('01111110' flag pattern).	R/W	0										
2:1	-	Reserved (0 for reads)	R	0										
0 (hdlc)	XCRC	Transmit CRC Checking Mode (hdlc) '0': The transmit checksum (2 or 4 bytes) is generated and appended to the transmit data. '1': The transmit checksum is not generated.	R/W	0										

Figure 6-26: Channel Configuration Register 2

6.5.6 BRR – Baud Rate Register (0x012C, 0x01AC, 0x022C, 0x02AC)

Bit	Symbol	Description	Access	Reset Value
31	BRGM	BRG Mode	R/W	0
30:21	-	Reserved (0 for reads)	R	0
20:0	BRD	Baud Rate Divisor	R/W	0

Figure 6-27: Baud Rate Register

These values determine the divisor of the baud rate generator. The baud rate generator input clock f_{in} depends on the selected clock source (see also chapters “Clock Sources” and “ACR - Additional Configuration Register”).

The resulting output frequency of the baud rate generator is:

$$f_{BRG} = f_{in} / k$$

The divisor k can be set in 2 ways, determined by BRR[31]. When BRR[31] = 0, k is calculated the former way as with the TCP862:

$$k = (N + 1) \times 2^M$$

with N (BRR[5:0]) = 0..63 and M (BRR[11:8]) = 0..15

The alternative is to set k directly as a 21-bit wide value BRD, when BRR[31] = 1.

When **asynchronous** mode is selected (register CCR0, bit BCR = '1'), k is **multiplied by 16**.

6.5.7 TCR – Termination Character Register (0x0148, 0x01C8, 0x0248, 0x02C8)

Bit	Symbol	Description	Access	Reset Value
31:16	-	Reserved (0 for reads)	R	0
15	TCDE	Termination Character Detection Enable (async./isochr.) '0': No receive termination character detection '1': Termination character detection is enabled. The receive data is analyzed for the termination character TC. When character is detected, a 'block end' and a 'TCDI' interrupt (if enabled) is generated.	R/W	0
14:8	-	Reserved (0 for reads)	R	0
7:0	TC	Termination Character (async./isochr.) Defines the termination character which is monitored on the receive data stream if enabled via bit 'TCDE'.	R/W	0

Figure 6-28: Termination Character Register

6.5.8 IMR – Interrupt Mask Register (0x0154, 0x01D4, 0x0254, 0x02D4)

Bit	Symbol	Description	Access	Reset Value
31:19	-	'0': interrupt is NOT masked, interrupt via INTA# IS generated '1': interrupt is masked, NO interrupt on INTA# generated	R	1
18	ALLS		R/W	1
17	-		R	1
16 (hdlc)	XDU		R/W	1
16 (asyn)	-		R	1
15	-		R	1
14	CSC		R/W	1
13:10	-		R	1
9 (asyn)	BRK		R/W	1
8 (asyn)	BRKT		R/W	1
7 (asyn)	TCD		R/W	1
6 (asyn)	TIME		R/W	1
5 (asyn)	PERR		R/W	1
4 (asyn)	FERR		R/W	1
9:4 (hdlc)	-		R	1
3	PLLA		R/W	1
2	CDSC		R/W	1
1	RFO		R/W	1
0	-		R	1

Figure 6-29: Interrupt Mask Register

Unused interrupts shall be masked to avoid unwanted behavior.

Especially CSC and CDSC should be masked if CTS and CD inputs are unconnected.

6.5.9 ISR – Interrupt Status Register (0x0158, 0x01D8, 0x0258, 0x02D8)

Bit	Symbol	Description	Access	Reset Value
31:19	-	Reserved (0 for reads)	R	0
18	ALLS	<p>ALL Sent Interrupt</p> <p>HDLC Mode: This bit is set to '1' if the last bit of the current HDLC frame is sent out via pin TxD,</p> <p>ASYNCR/ISOCHR Mode: This bit is set to '1', if the last character is completely sent via pin TxD and no further data is stored in the SCC transmit FIFO, i.e. the transmit FIFO is empty.</p>	R/C	0
17	-	Reserved (0 for reads)	R	0
16 (hdlc)	XDU	<p>Transmit Data Underrun Interrupt (hdlc)</p> <p>HDLC Mode: This bit is set to '1', if the current frame was terminated by the SCC with an abort sequence, because neither a 'frame end / block end' indication was detected in the FIFO (to complete the current frame) nor more data is available in the SCC transmit FIFO.</p> <p><i>Note: The transmitter is stopped if this condition occurs and needs to be reset via command bit 'XRES' in register CMDR.</i></p>	R/C	0
16 (asyn)	-	Reserved (0 for reads)	R	0
15	-	Reserved (0 for reads)	R	0
14	CSC	<p>CTS# Status Change Interrupt</p> <p>This bit is set to '1', if a transition occurs on signal CTS#. The current state of signal CTS# is monitored by status bit 'CTS' in status register STAR.</p>	R/C	0
13:10	-	Reserved (0 for reads)	R	0
9 (asyn)	BRK	<p>Break Interrupt (asyn./isochr.)</p> <p>This bit is set to '1', if a break condition was detected on the receive line, i.e. a low level for a time equal to (character length + parity bit + stop bit(s)) bits depending on the selected ASYNCR character format.</p>	R/C	0
8 (asyn)	BRKT	<p>Break Terminated Interrupt (asyn./isochr.)</p> <p>This bit is set to '1', if a previously detected break condition on the receive line is terminated by a low to high transition.</p>	R/C	0
7 (asyn)	TCD	<p>Termination Character Detected Interrupt (asyn./isochr.)</p> <p>This bit is set to '1', if a termination character is detected in the receive data stream. The SCC will insert a 'frame end / block end' indication to the SCC receive FIFO which causes the DMAC to finish the current receive descriptor.</p>	R/C	0
6 (asyn)	TIME	<p>Time Out Interrupt (asyn./isochr.)</p> <p>This bit is set to '1', if the time out limit is exceeded, i.e. no new character was received in a programmable period of time (refer to register CCR1 bit fields 'TOIE' and 'TOLEN' for more information).</p>	R/C	0

Bit	Symbol	Description	Access	Reset Value
5 (asyn)	PERR	Parity Error Interrupt (asyn./isochr.) This bit is only valid if parity checking/generation is enabled via bit 'PARE' in register CCR2. It is set to '1', if a character with wrong parity has been received. If enabled via bit 'RFDF', this error status is additionally stored in the receive status byte generated for each receive character.	R/C	0
4 (asyn)	FERR	Frame Error Interrupt (asyn./isochr.) This bit is set to '1', if a character framing error is detected, i.e. a '0' was sampled at a position where a stop bit '1' was expected due to the selected character format.	R/C	0
9:4 (hdlc)	-	Reserved (0 for reads)	R	0
3	PLLA	DPLL Asynchronous Interrupt This bit is only valid, if the receive clock is derived from the internal DPLL and FM0, FM1 or Manchester data encoding is selected (depending on the selected clock source and data encoding mode). It is set to '1' if the DPLL has lost synchronization. Reception is disabled until synchronization has been regained again. If the transmitter is supplied with a clock derived from the DPLL, transmission is also interrupted.	R/C	0
2	CDSC	Carrier Detect Status Change Interrupt This bit is set to '1', if a state transition has been detected at signal CD. Because only a state transition is indicated via this interrupt, the current status can be evaluated by reading bit 'CD' in status register STAR.	R/C	0
1	RFO	Receive FIFO Overflow Interrupt This bit is set to '1', if receive data got lost because of a SCC receive FIFO full condition.	R/C	0
0	-	Reserved (0 for reads)	R	0

Figure 6-30: Interrupt Status Register

**If CCR0.VIS is set to '1' then masked interrupt status bits will be visible in the ISR.
To clear these interrupt flags, the host CPU must write '1' to the corresponding ISR bit.**

6.5.10 ACR – Additional Configuration Register (0x015C, 0x01DC, 0x025C, 0x02DC)

Bit	Symbol	Description	Access	Reset Value
31:20	-	Reserved (0 for reads)	R	0
19	ETRBO	Extended Transparent mode Receive Bit Order '0': Receive Data is LSB first (first received bit at position 0) '1': MSB first (first received bit at position 7) <i>Note: Setting this bit to '1' might be useful to detect special characters more easily by software in the receive data stream. After detection of the byte alignment, the bits in each byte have to be mirrored to get the original data bytes.</i>	R/W	0
18	DTR3	Data Terminal Ready Channel 3 (Only on channel 3!)	R/W	0
17	CDOUT	CD Output Value	R/W	0
16	CDDIR	CD Direction '0': CD is input '1': CD is output	R/W	0
15	DCMRST	Reset the Clock Multiplier '0': Clock Multiplier is running '1': Clock Multiplier is held in Reset <i>Note: The Clock Multiplier should always be reset after changing its input clock</i>	R/W	0
14	X4MULT	Multiply BRG Input Clock x4 '0': No clock frequency change '1': BRG input clock frequency is multiplied by 4 <i>Note: The input frequency range of the x4 clock multiplier is 4.5 MHz to 28 MHz, these values must never be exceeded to ensure proper function of the clock multiplier.</i>	R/W	0
13	RXCINV	Invert RxC '0': No inverting of RxC '1': RxC is inverted	R/W	0
12	TXCINV	Invert TxC '0': No inverting of TxC '1': TxC is inverted	R/W	0

Bit	Symbol	Description	Access	Reset Value
11:10	RCS	Receiver Clock Source '00': BRG Output Clock '01': external RxC Input signal '10': DPLL Output Clock '11': reserved	R/W	00
9:7	TCS	Transmitter Clock Source '000': BRG Output Clock '001': external RxC Input signal '010': external TxC (Input direction, CCR0.TOE=0) '011': DPLL Output Clock '100': BRG Output Clock divided by 16 others: reserved	R/W	000
6:4	BCS	BRG Clock Source '000': Oscillator 1 Clock 14.7456 MHz '001': Oscillator 2 Clock 24 MHz '010': Oscillator 3 Clock 10 MHz '011': external RxC Input signal '100': external TxC (Input direction, CCR0.TOE=0) others: reserved	R/W	000
3	RTSCLK	Enable TxC Output on RTS pin '0': No TxC Output on RTS (normal function) '1': TxC Output Enabled on RTS	R/W	0
2:0	MODE	Transceiver Mode (M2:M0, see following table)	R/W	111

Figure 6-31: Additional Configuration Register

The input frequency range of the x4 clock multiplier is 4.5 MHz to 28 MHz, these values must never be exceeded to ensure proper function of the clock multiplier.

Transceiver Mode	M2	M1	M0	Driver/Receiver Mode
Not Used (Default V.11)	0	0	0	TxD,TxC,RxD,RxC,RTS,CTS,CD: V.11
EIA-530A	0	0	1	TxD,TxC,RxD,RxC,RTS,CTS,CD: V.11
EIA-530	0	1	0	TxD,TxC,RxD,RxC,RTS,CTS,CD: V.11
X.21	0	1	1	TxD,TxC,RxD,RxC,RTS,CTS,CD: V.11
V.35	1	0	0	TxD,TxC,RxD,RxC: V.35 / RTS,CTS,CD: V.28
EIA-449/V.36	1	0	1	TxD,TxC,RxD,RxC,RTS,CTS,CD: V.11
V.28/EIA-232	1	1	0	TxD,TxC,RxD,RxC,RTS,CTS,CD: V.28
No Cable (high impedance)	1	1	1	TxD,TxC,RxD,RxC,RTS,CTS,CD: Z

Figure 6-32: Physical Interface Mode Selection

7 Configuration Hints

7.1 Big / Little Endian

PCI – Bus (Little Endian):

Byte 0	AD[7..0]
Byte 1	AD[15..8]
Byte 2	AD[23..16]
Byte 3	AD[31..24]

The TCP863 expects all accesses by the host and all data structures in the host RAM to be 'Little Endian'.

Transmit data in lower bytes is sent first.

Receive data that was received earlier is stored at lower bytes.

7.2 Configuration EEPROM

An industry standard M93C56 serial EEPROM with 2 Kbit is connected to the FPGA and can be accessed through the GCTLR register. The EEPROM is configured for word (16 bit) accesses.

The addresses 0x00..0x5F are factory programmed with configuration information used by the software drivers and **must not be overwritten**. The other addresses (0x60..0x7F) are user programmable.

The configuration EEPROM contains the following data:

- Vendor ID
- Vendor Device ID
- Subsystem Vendor ID
- Subsystem Device ID
- The module version and revision
- The oscillator frequencies in Hz
- The physical interface attached to the serial channels
- The maximal baud rate of the transceivers in bps
- The supported control signals of the serial channels

For the physical interfaces and the control signals applies: Bit 3 represents UART channel 3 and bit 0 represents UART channel 0. The appropriate bit is set to '1' for each UART channel attached to the physical interface represented by the word. Bit 15 to bit 4 are always '0'.

Address	Configuration Register	TCP863
0x00	Vendor ID	0x1498
0x01	Device ID	0x235F
0x02	Subsystem Vendor ID	0x1498
0x03	Subsystem ID	s.b.

7.3 Additional Termination Resistors

The Rx-/Tx-Clock and Data lines are connected to LTC1546 transceivers with internal termination; the control lines (RTS, CTS, CD) are connected to LTC1544 without termination, as termination of these signals is not necessary in the normal case. If the application requires termination of these lines standard 120Ω resistors in 0603 package can be mounted on the provided pads (see following two figures for assignment and positions).

Signal	Resistor
CTS0	R4
CD0	R5
RTS0	R6
CTS1	R12
CD1	R13
RTS1	R14

Signal	Resistor
CTS2	R1
CD2	R2
RTS2	R3
CTS3	R9
CD3	R10
RTS3	R11
